

Policy for the Ultrasound Management of Incidentally Detected Liver Haemangiomas

- Cavernous liver haemangiomas are common (present in 4%) of the population.
- They are a common incidental finding on abdominal ultrasound examination.
- In patients at low risk of hepatic malignancy, where ultrasound appearances are typical and lesions are less than 3cm, the risk of mistaking a hepatic malignancy for a haemangioma is extremely remote.
- This policy aims to standardise the ultrasound management of such lesions.

Incidental liver lesion typical of haemangioma.
Characteristic features include all of the following:

- Well-defined.
- Uniformly echogenic with no echo poor halo.
- Homogenous.
- No discernable internal blood flow.

**>3cm in diameter
and/or**

Risk Factors for hepatic malignancy.

- Previous or current extra-hepatic malignancy.
- Clinically known or suspected chronic liver disease.
- Abnormal liver function tests
- Abnormal liver echogenicity or morphology at ultrasound
- Lesion not seen at previous imaging

Consultant review of imaging*. Further imaging according to local policies (CEUS/MRI/CT)

***Where ultrasound has been performed in the primary care setting, suggest referral to imaging in secondary care. Additional imaging to be determined by vetting radiologist.**

No risk factors for hepatic malignancy AND solitary lesion, 3cm or less in diameter.

Report as haemangioma. No follow-up advocated.

**Report should read;
'ultrasound findings are consistent with a haemangioma and require no further evaluation, provided that the patient has no prior or current evidence of malignancy or chronic liver disease.'**

**Short code on CRIS
Press 'Alt' and 'p' then type
haem**
